

kokchun giang

**data & multiple
containers** are
important when
dockerizing you entire
application

where is my **data**?

yes apparently it
disappears after shutting
down the container

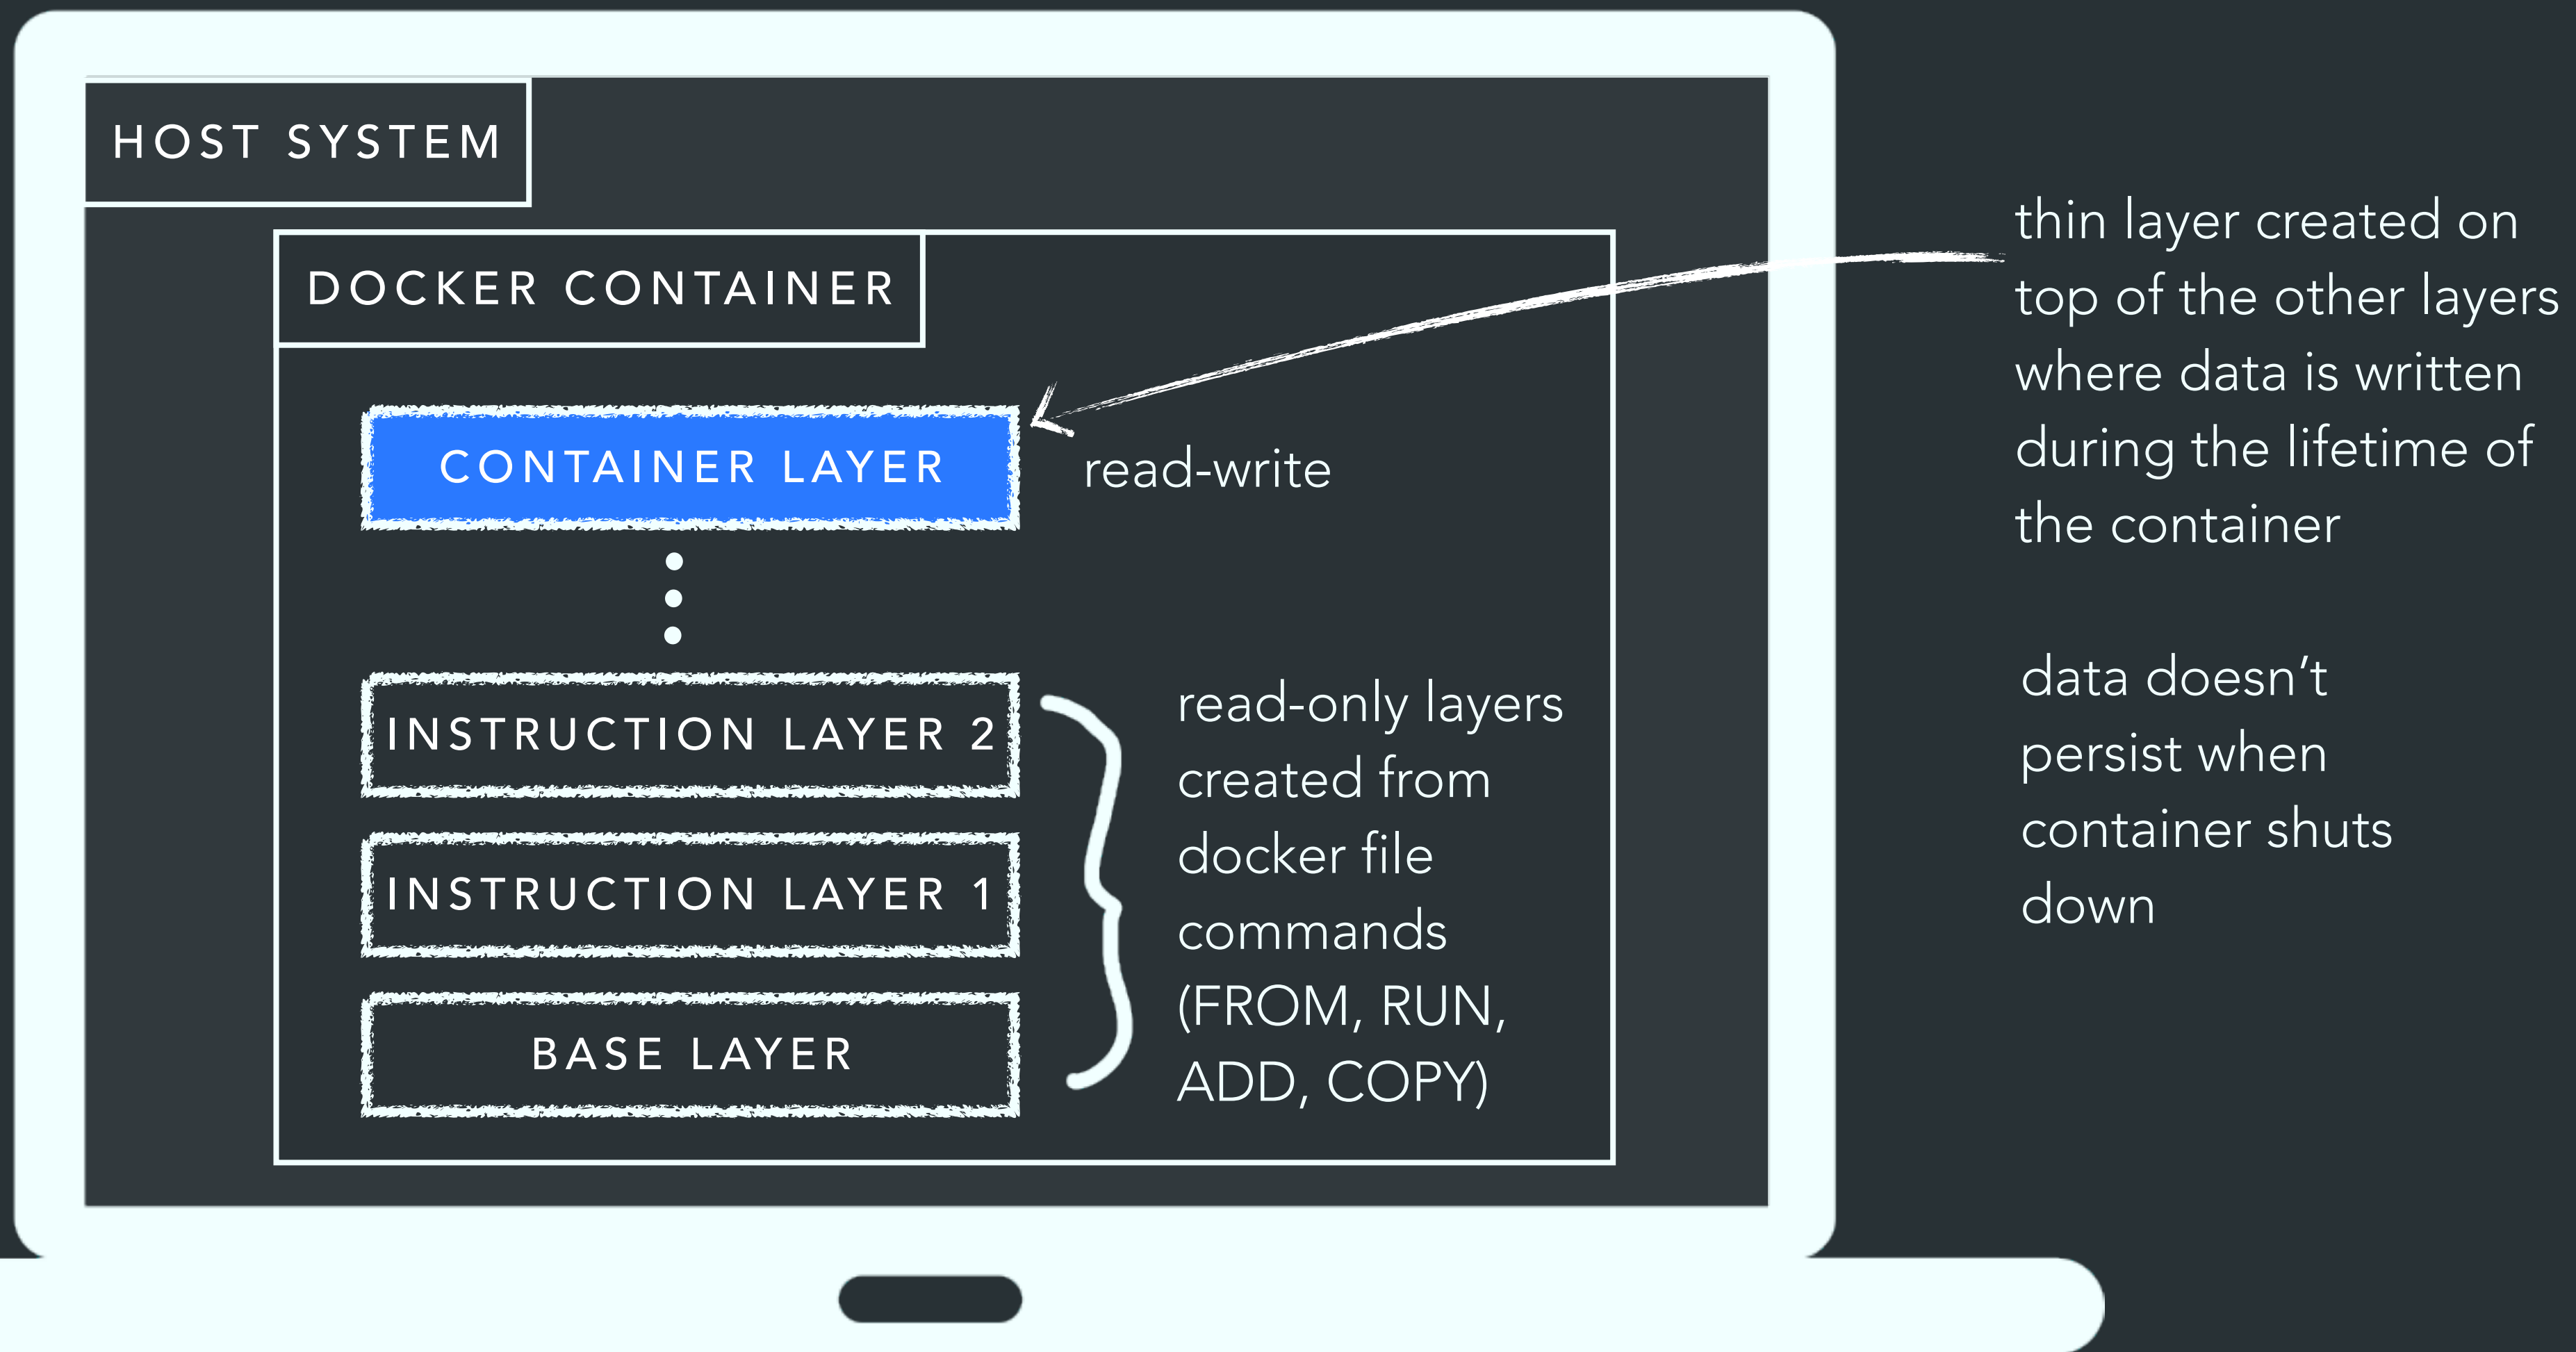

you said docker containers
were great, so where is my
data dude?

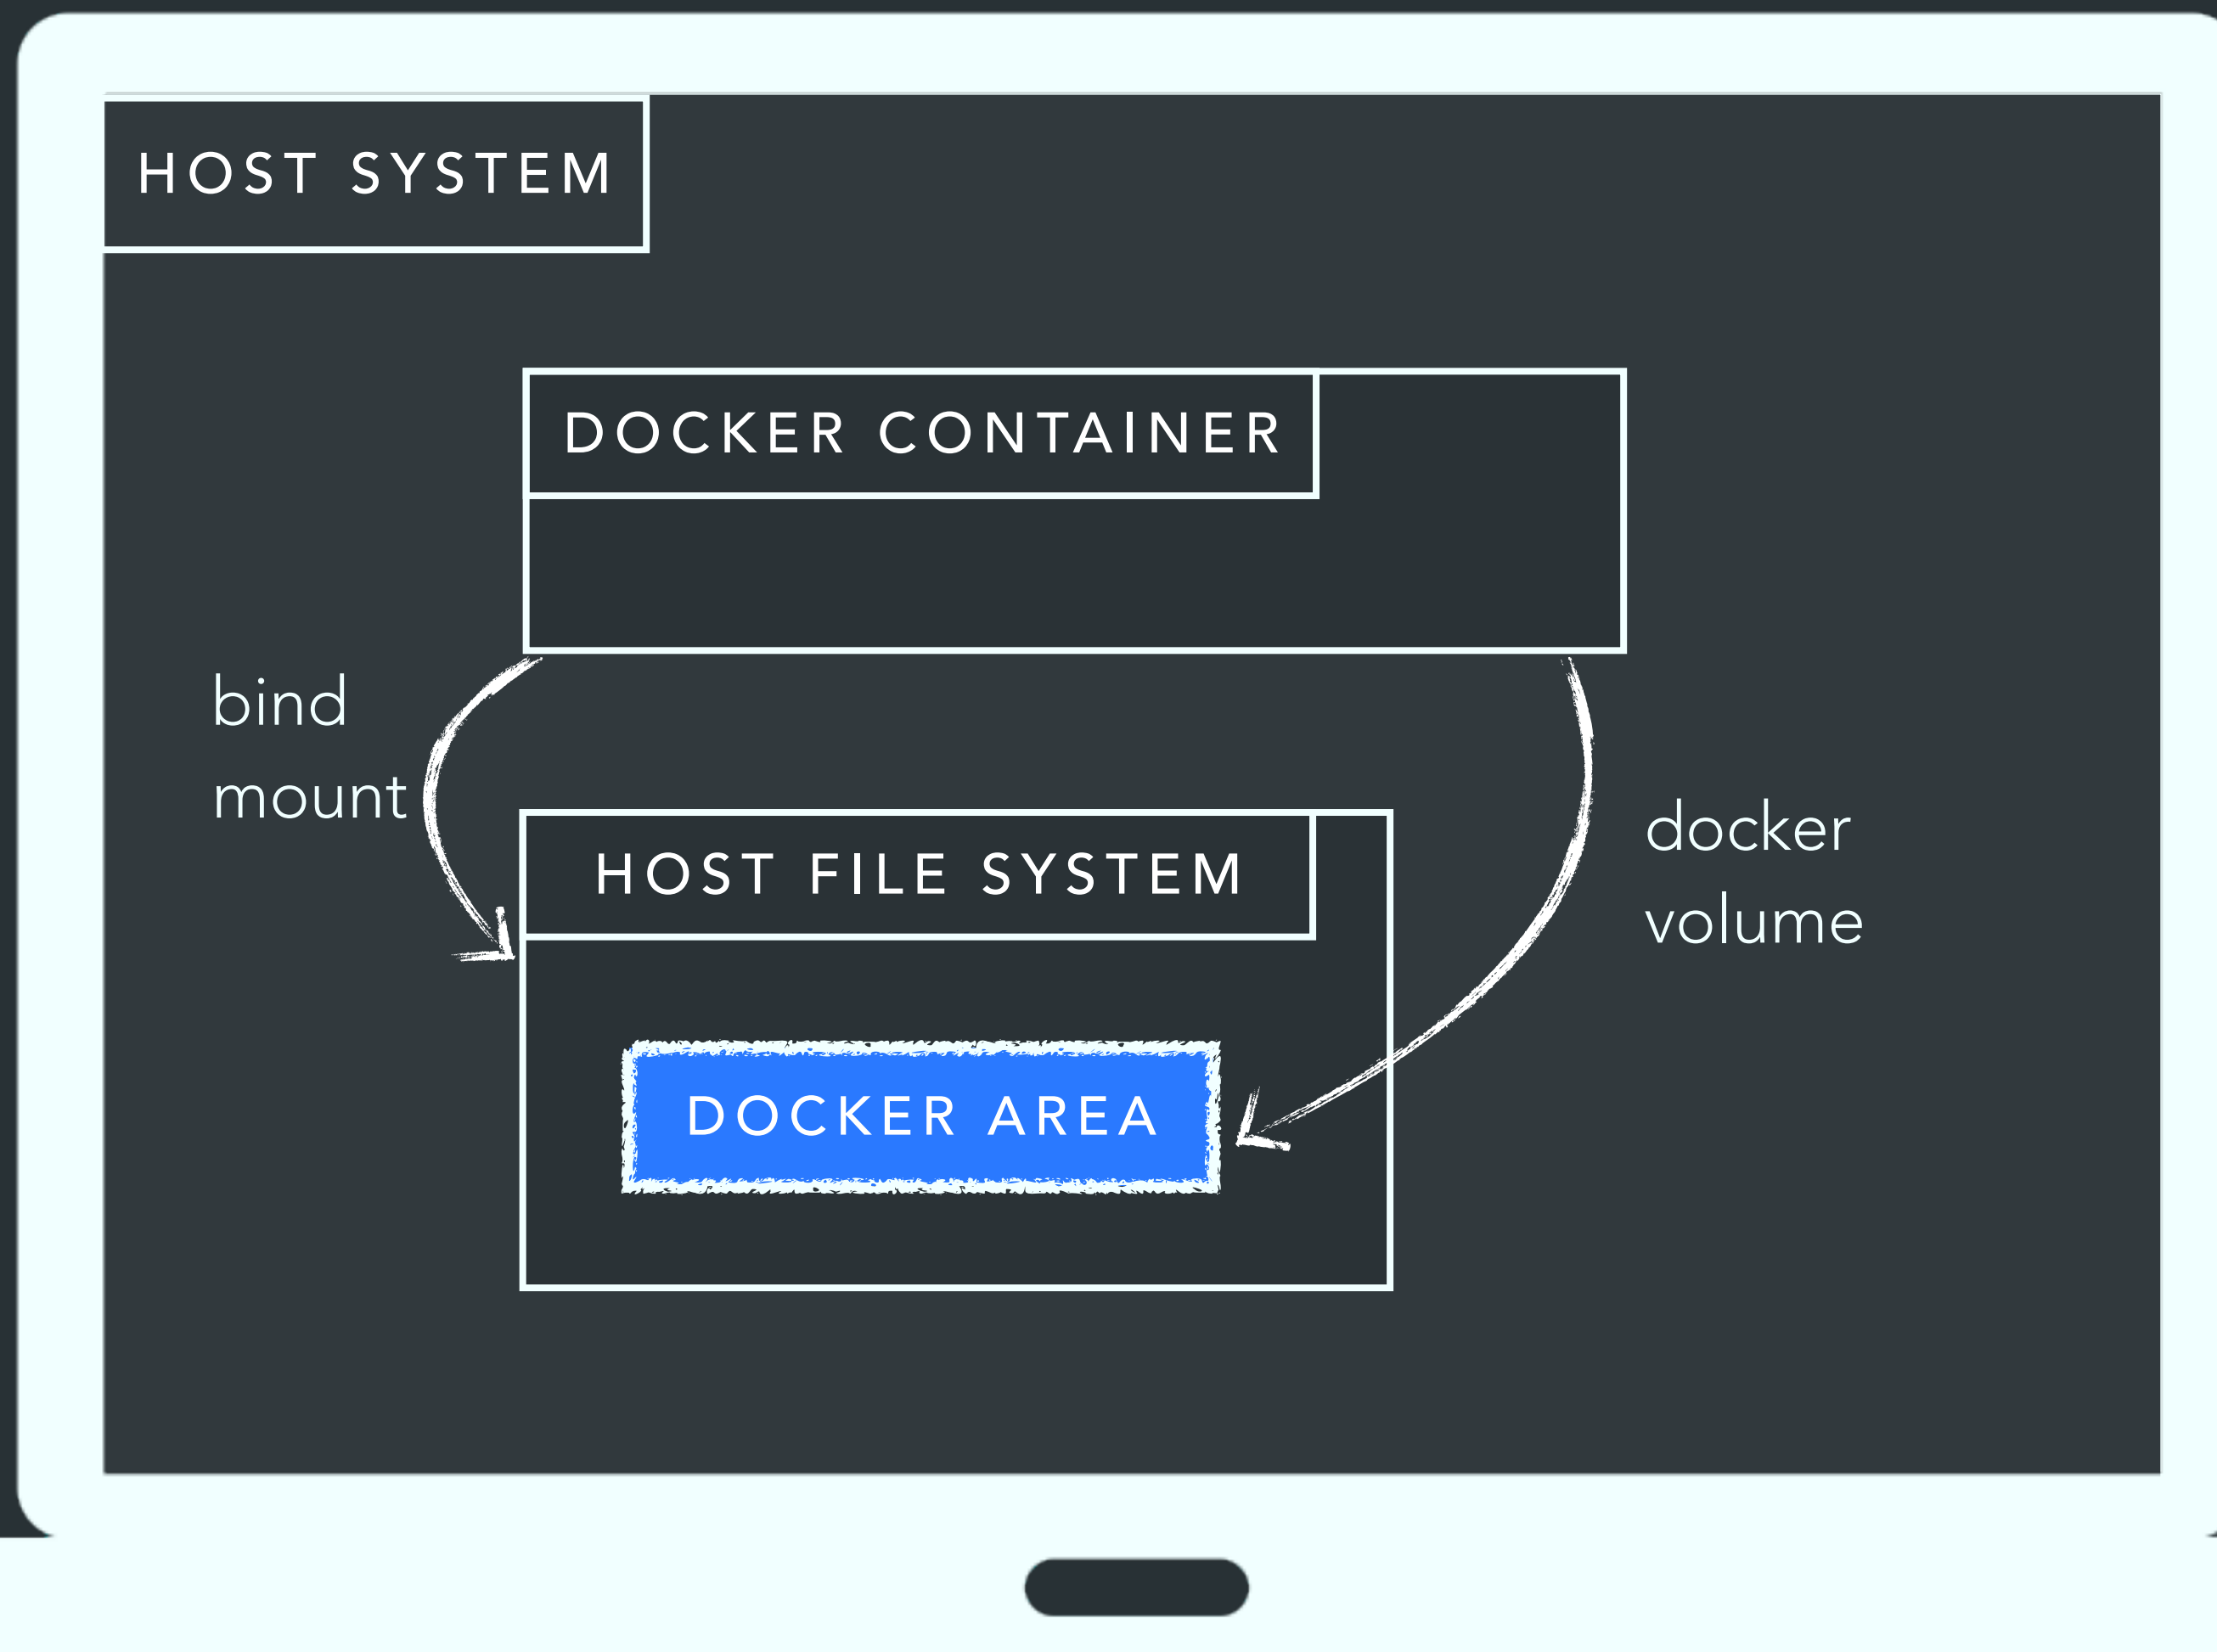

use me to pick the locks
of the container and
look inside the hood

what if there was an **environment** that works for everyone?

volumes & bind mount to persist data

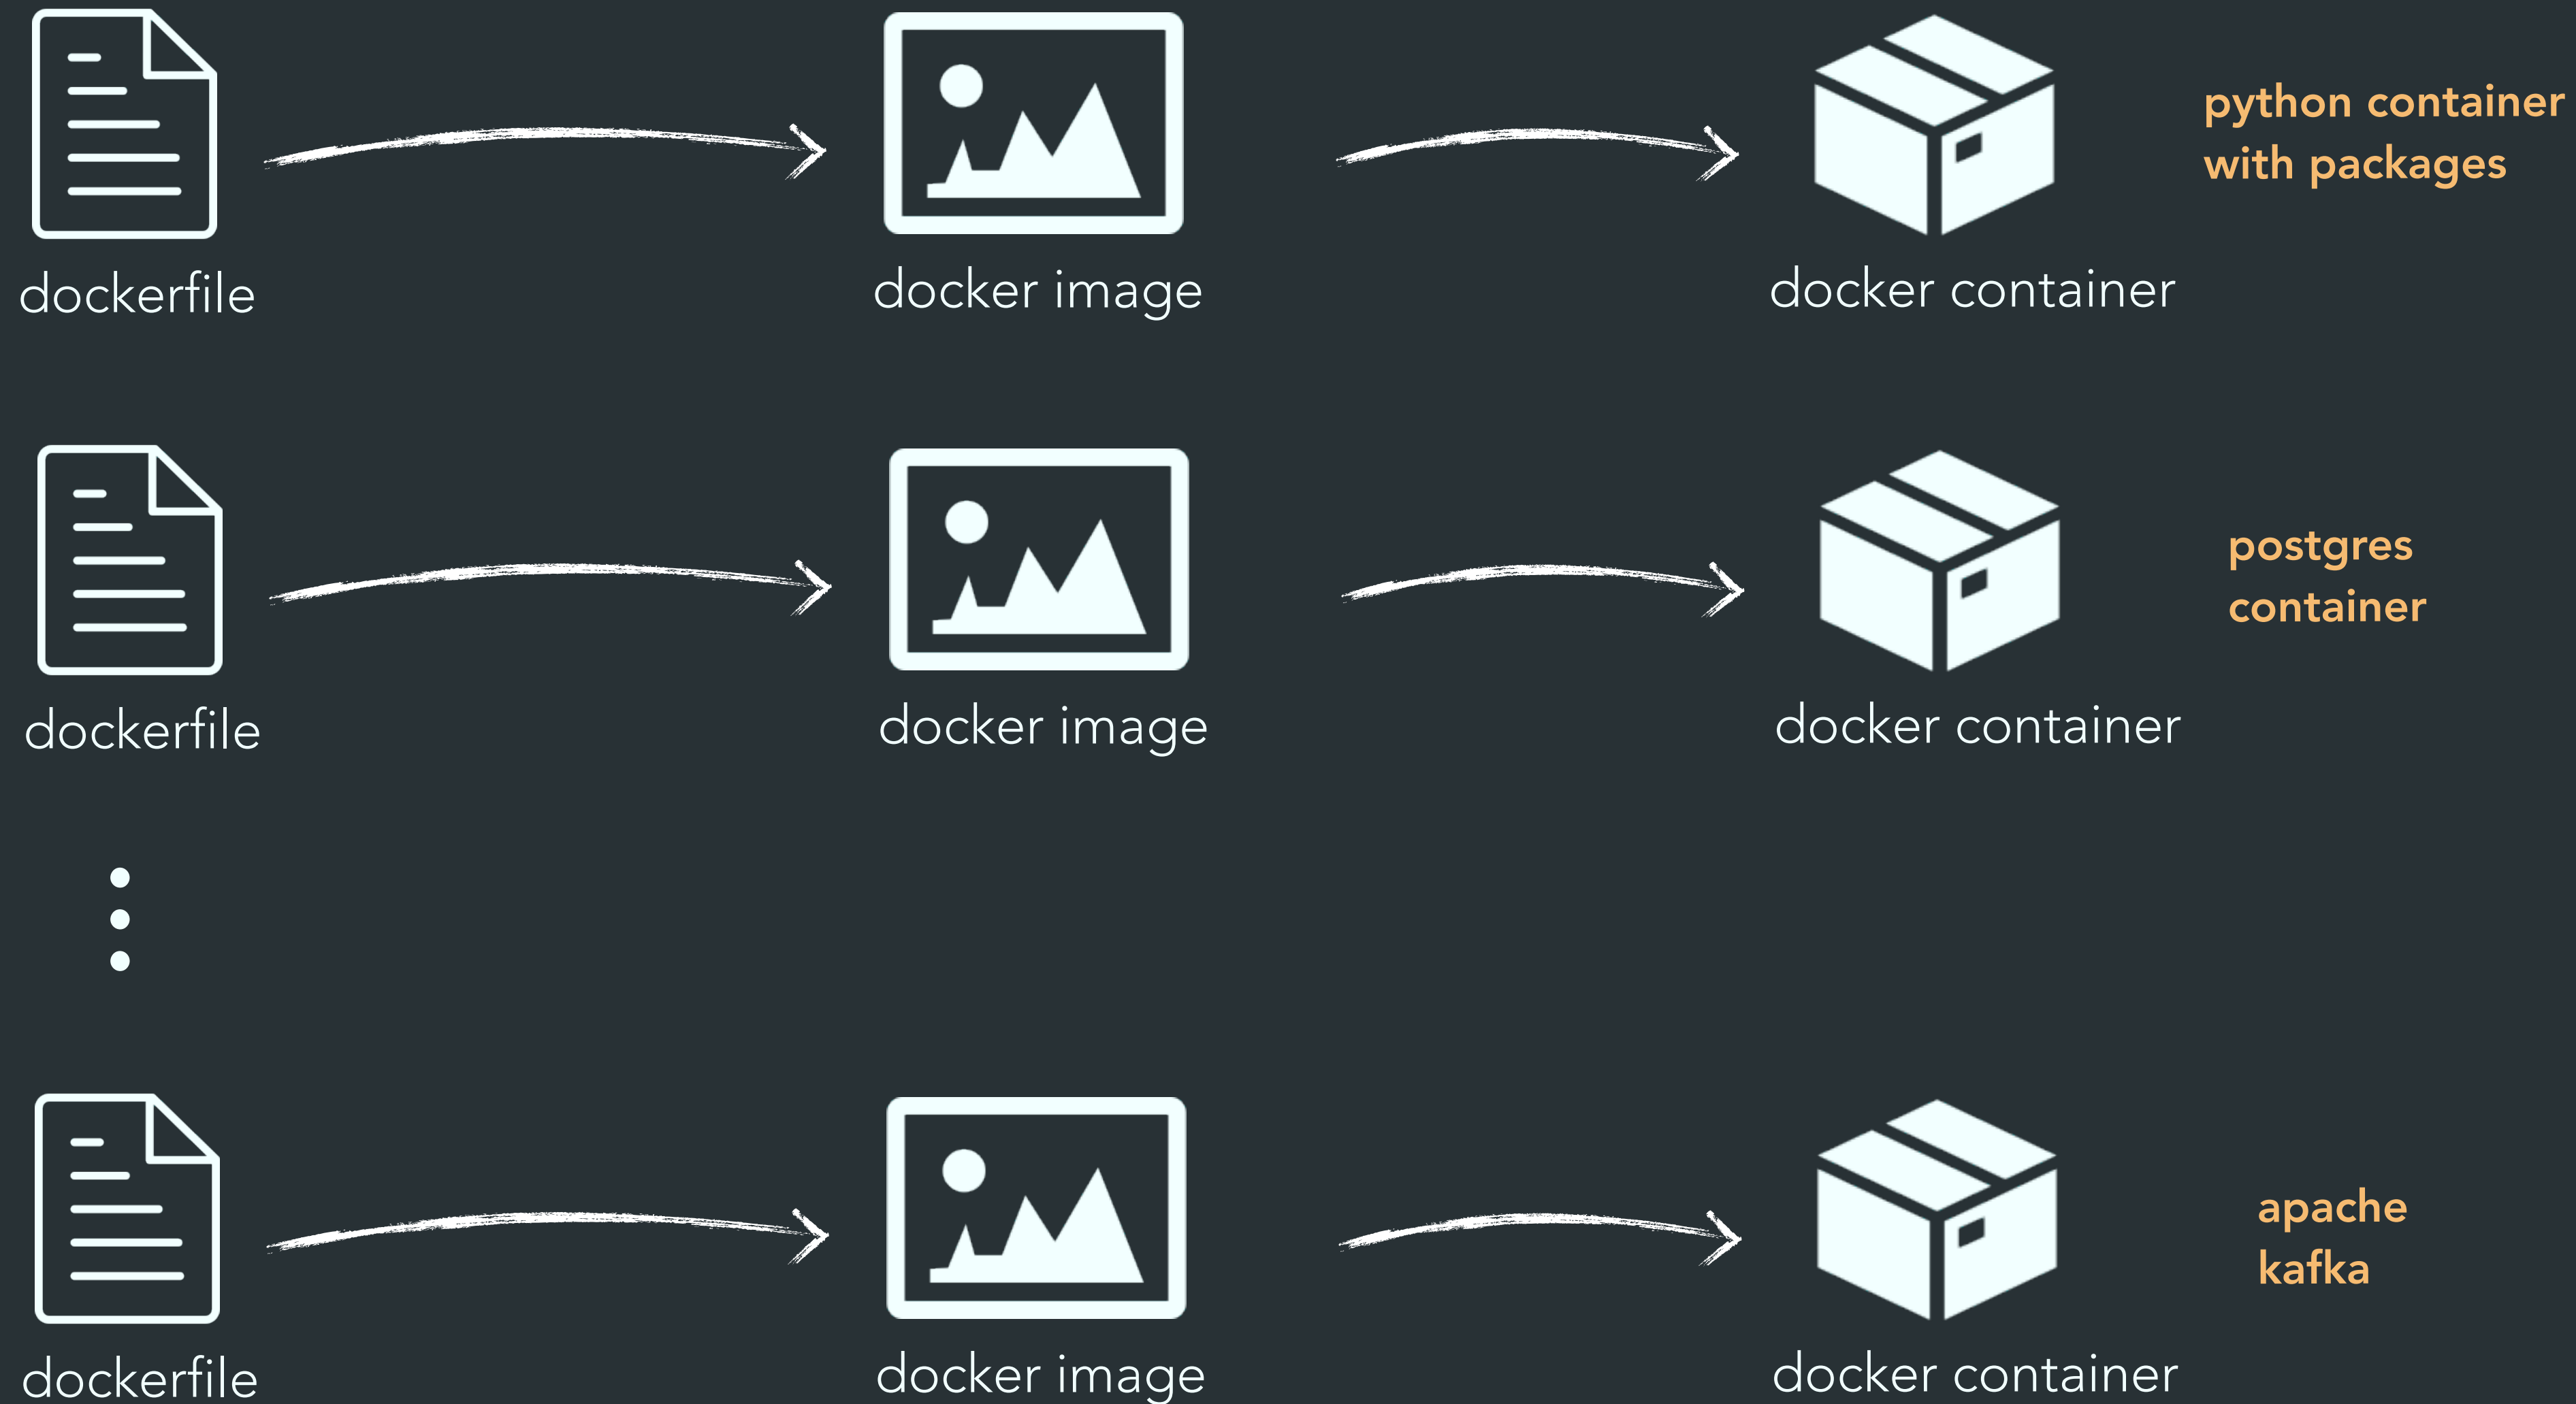

volumes

stored in certain place in host and managed by docker

bind mounts

stored anywhere in host filesystem

separate into several **docker containers** for scalability

so many **dockerfiles** ...

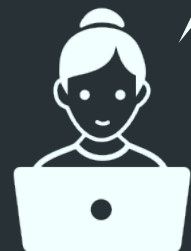

arghhh so many files to
keep track of

use paper clip to put the
together :)

nah, we can use one
master file instead -
docker compose

multiple **docker containers** using **docker-compose**
